In recent years, environmental issues have been the focus of attention in the fields of automobiles and electric products. As vehicles and home appliances, batteries used as power supply sources have been required to have a higher output and a smaller size, a low cost, and safety. In response to these requirements, batteries using a composite lithium-containing oxide as a positive electrode active material and a transition metal oxide or lithium-containing oxide as a negative electrode active material have been actively studied (see Patent Literature 1, for example). Such a battery is formed by interposing an electrolyte between a positive electrode and a negative electrode. On the other hand, a battery formed by interposing an electrolyte between a positive electrode and a negative electrode is used as a battery module in a large-capacity electric vehicle, a battery pack for motor-driven power steering, a mobile phone, an electric tool, or the like. In this case, the battery module includes a plurality of batteries connected in series so as to increase the capacity and output. In addition, there is also a widespread use of a battery module in which an additional electrical circuit is added to a battery in order to achieve a circuit control or to realize specific functions. For example, a battery module used in, for example, a hybrid automobile includes a current interrupt device (CID) provided for each cell to achieve improved safety and to suppress inrush current at the time of starting. In addition, a battery module used in a large-capacity electric vehicle includes a battery control circuit to control the charging and discharging and to measure the internal temperature and state of a battery cell, and a battery control circuit unit such as a module for determining the type of the

battery cell. For a battery module including both of such circuits, for example, a battery module (unit) is disclosed in which a plurality of battery control circuit units are connected in parallel (see Patent Literature 2).
